

### Abstract

Nutrition complications are common in survivors of the rare, life-threatening anomaly congenital diaphragmatic hernia (CDH). Infants diagnosed with CDH may require feeding tubes and gastroesophageal reflux treatment yet still demonstrate poor growth. This literature review was conducted to determine nutrition interventions resulting in favorable growth which may improve outcomes in these infants. Results indicate that early nutrition support including supplemental parenteral nutrition with calorie and protein provisions of  $\geq 125$  kcal/kg and  $\geq 2.3$  g/kg protein may have a positive impact on growth, potentially impacting neurological development.

### Introduction / Methods

- Multiple studies documenting growth difficulties in DH
- Few studies with guidelines to help improve outcomes
- Literature review\* with only 5 studies that answered PICO question
  - Most studies weak design – retrospective cohort
- Opportunities for future research

\*Conducted in 2019

### Conclusions

- Plan for nutrition > RDA for age
  - Most infants will be hypermetabolic
  - $\geq 125$  kcal/kg
  - $\geq 2.3$  g/kg
- Aggressive early PN
- Cautious transition to EN
- Longer PN may improve growth outcomes
